# International Young Mathematicians' Convention (IYMC) 2012 Team Contest – Senior level

1. In the figure,  $E$  is a point inside the square  $ABCD$  such that  $BE=CE$  and  $\angle BEC = 150^\circ$ . Prove that  $\triangle ADE$  is an equilateral triangle.

**【Solution 1】**

Draw  $\triangle FAB$  in left part of the square so that

$\triangle FAB \cong \triangle EBC$ . Thus  $BF = BE$ .

$$\angle FBE = 90^\circ - 15^\circ - 15^\circ = 60^\circ.$$

Since  $BF = BE$ , hence  $\triangle BEF$  is an equilateral triangle.

Thus  $AF = FE$ .

We get  $\angle AFE = 360^\circ - 60^\circ - 150^\circ = 150^\circ$ .

Hence  $\angle FAE = \angle AEF = 15^\circ$ , and  $\angle EAD = 90^\circ - 15^\circ - 15^\circ = 60^\circ$ .

Since  $AB=AE=AD$ , hence we get  $\triangle ADE$  is an equilateral triangle.

**【Solution 2】**

Let  $M$  and  $N$  be the midpoint of  $BC$  and  $AD$ , respectively.

Thus  $MN$  is the perpendicular bisector of  $BC$  and hence  $E$  is on  $MN$ .

We can find a point  $E'$  on  $MN$  such that  $AE' = AB$ .

Then  $DE' = AE' = AB = AD$ , i.e.  $\triangle AE'D$  is an equilateral triangle.

So  $\angle BAE' = 90^\circ - 60^\circ = 30^\circ$ .

We get that  $\angle ABE' = \angle AE'B = \frac{180^\circ - 30^\circ}{2} = 75^\circ$ .

Hence  $\angle E'BC = 90^\circ - \angle ABE' = 15^\circ$ .

Thus  $E$  and  $E'$  are coincide, we get  $\triangle ADE$  is an equilateral triangle.

2. The figure shows a polyhedron in which each vertex lies on one regular decagon, one regular hexagon and one square. If this polyhedron have  $V$  vertices,  $E$  edges,  $F$  faces, find the value of  $V+E+F$ .

**【Solution】**

The sum of the angles that meet at each vertex is:

$$144 + 120 + 90 = 360 - \frac{720}{V}$$

$$V = 120$$

Suppose there are  $x$  decagons,  $y$  hexagons, and  $z$  squares.

Three faces intersect at each vertex, so we have  $120 \times 3 = 10x + 6y + 4z$ .

Each decagon is adjacent to five hexagons, and each hexagon is adjacent to three

decagons. Therefore, we get  $5x = 3y$ .

Each decagon is adjacent to five squares, and each square is adjacent to two decagons. Therefore, we get  $5x = 2z$ .

Hence we know  $x=12$ ,  $y=20$  and  $z=30$ .

So  $V=120$ ,  $E=(12 \times 10 + 6 \times 20 + 4 \times 30) \div 2 = 180$  and  $F=12+20+30=62$ .

Thus  $V+E+F=120+180+62=362$ .

**Answer: 362**

3. Five boxes contain 120 coins in all. Some are golden coins, some are silver coins and the rest are copper coins. Any two boxes contain less than 30 golden coins. Any three boxes contain less than 20 silver coins. Prove that some four boxes contain at least 15 copper coins.

**【Proof】**

Ordering all boxes in increasing order with respect to the amount of golden coins they contain. The fourth and fifth boxes contain less than 30 golden coins so the fourth box contains not more than 14 golden coins.

Thus so does first, second and third boxes. Then total amount of golden coins is at most  $71 = 14+14+14+29$ .

In a similar way order all boxes in increasing order with respect to the amount of silver coins they contain. The third, fourth and fifth boxes contain less than 20 silver coins so the third one contains not more than 6 silver coins.

Thus so does first and second boxes. Then total amount of silver coins is at most  $31 = 6+6+19$ . We get the total amount of copper coins is at least  $120 - 71 - 31 = 18$ .

Let's order all boxes in increasing order with respect to the amount of copper coins they contain. The first box contain no more than  $18 \div 5 = 3.6$  copper coins so the other four boxes contain at least 15 coins.

4. A man uses a gold chain consisted of 159 links to repay a debt. By agreement, he must hand in one link per week. He may hand in more links if he can get exact change. The debt is paid when all 159 links have been handed in. What is the minimum number of links that must be broken?

**【Solution】**

Note that when a link in the center of the chain is broken, three pieces are obtained: a one-link piece and two other pieces.

If he only broken 1 link, then there must have a 2-link piece and hence another one is a 156-link piece. Thus he can't get 4.

If he only broken 2 links, then there must have a 3-link piece, a 6-link piece and hence the other one is a 148-link piece. Thus he can't get 12.

If he only broken 3 links, then there must have a 4-link piece, a 8-link piece, a 16-link piece and hence the other one is a 128-link piece. Thus he can't get 32.

So the minimum number of links that must broken is 4.

If he broken the 6<sup>th</sup>, 17<sup>th</sup>, 38<sup>th</sup> and 79<sup>th</sup> link. This would result in 4 one-link pieces, one 5-link piece, one 10-link piece, one 20-link piece, one 40-link piece, and one 80-link piece.

Using those pieces he can pay any debt from 1 to 159.

**Answer: 4 links**

5. The sequence  $\{f(1), f(2), f(3), \dots\}$  of increasing positive integers satisfies  $f(f(n)) = 3n$ . Find the value of  $f(2012)$ .

**【Solution 1】**

We prove the following lemma.

**<Lemma>** For  $n=0, 1, 2, \dots$ , (1)  $f(3^n) = 2 \times 3^n$  and (2)  $f(2 \times 3^n) = 3^{n+1}$ .

We use induction. For  $n=0$ , note that  $f(1) \neq 1$ , otherwise  $3 = f(f(1)) = f(1) = 1$ , which is impossible. Since  $f: \mathbb{N} \rightarrow \mathbb{N}$ ,  $f(1) > 1$ , and  $f(n+1) > f(n)$ ,  $f$  is increasing. Thus  $1 < f(1) < f(f(1)) = 3$  or  $f(1) = 2$ . Hence  $f(2) = f(f(1)) = 3$ .

Suppose that for some positive integer  $n \geq 1$ ,  $f(3^n) = 2 \times 3^n$  and  $f(2 \times 3^n) = 3^{n+1}$ .

Then  $f(3^{n+1}) = f(f(2 \times 3^n)) = 2 \times 3^{n+1}$  and  $f(2 \times 3^{n+1}) = f(f(3^{n+1})) = 3^{n+2}$  as desired.

This completes the induction.

There are  $3^n - 1$  integers  $m$  such that  $3^n < m < 2 \times 3^n$  and there are  $3^n - 1$  integers  $m'$  such that  $f(3^n) = 2 \times 3^n < m' < 3^{n+1} = f(2 \times 3^n)$ .

Since  $f$  is an increasing function,  $f(3^n + m) = 2 \times 3^n + m$  for  $0 \leq m \leq 3^n$ . Therefore

$$f(2 \times 3^n + m) = f(f(3^n + m)) = 3(3^n + m) \text{ for } 0 \leq m \leq 3^n.$$

Hence  $f(2012) = f(2 \times 3^6 + 554) = 3(3^6 + 554) = 3849$

**【Solution 2】**

For integer  $n$ , let  $n_{(3)} = a_1 a_2 \dots a_l$  denote the base 3 representation of  $n$ . Using similar induction as in the first solution, we can prove that

$$f(n)_{(3)} = \begin{cases} 2a_2 \dots a_l & \text{if } a_1 = 1 \\ 1a_2 \dots a_l 0 & \text{if } a_1 = 2 \end{cases}$$

Since  $2012_{(3)} = 2202112$ ,  $f(2012)_{(3)} = 12021120$  or

$$f(2012) = 1 \times 3^7 + 2 \times 3^6 + 2 \times 3^4 + 1 \times 3^3 + 1 \times 3^2 + 2 \times 3^1 = 3849. \quad \text{ANS: 3849}$$

6. In the figure,  $P$  and  $Q$  are two distinct points inside the acute triangle  $ABC$ .

If  $\angle APB = \angle BPC = \angle CPA = 120^\circ$ . Prove that  $PA + PB + PC < QA + QB + QC$ .

**【Solution】**

Find perpendicular lines to  $PA, PB, PC$  through points  $A, B, C$ ; and the perpendicular lines intersect at  $M, N, L$ . We know that the interior angles of  $\triangle MNL$  are all  $60^\circ$ , hence  $\triangle MNL$  is an equilateral triangle.

Since any point in an equilateral triangle has constant sum of distances from the point to 3 perpendicular lines (If  $\triangle MNL$  has height  $h$ , since  $a\triangle MNL = a\triangle PLM + a\triangle PMN + a\triangle PNL$ ,  $(PA + PB + PC) MN/2 = h MN/2$ .

So we know  $PA + PB + PC = h$  is constant.)

The point  $Q$  is different to  $P$ , through  $Q$  we find  $QA' \perp ML$ ,  $QB' \perp NL$ , and  $QC' \perp MN$ .

By properties of right triangles:  $QA' < QA$ ,  $QB' < QB$ , and  $QC' < QC$ , then  $PA + PB + PC = QA' + QB' + QC' < QA + QB + QC$ .
